Smollan Digital Commerce — AI-powered Ecommerce Audit & Lead Generation

My recommendation is to build a website audit platform that doubles as a sales prospecting tool. A prospective client enters their website URL, the application examines the accessible pages, evaluates the customer journey, identifies conversion barriers, and generates a branded report resembling your Reebok example — but with stronger evidence, more granular scoring, and a commercially useful action plan.

The important distinction is that this should not simply be an AI tool that looks at a homepage and invents a score. It should combine website crawling, browser-based inspection, technical measurements, structured scoring rules, and Gemini's analysis to produce defensible findings.

Google AI Studio's Build mode supports full-stack web applications with a React frontend, a Node.js server runtime, npm packages and server-side secrets. That makes it a reasonable starting point for this application.

1. The proposed application

01 — Website Intelligence. Enter a domain, discover its sitemap and internal links, classify pages, inspect navigation and page elements, and identify the most important customer journeys.

02 — UX/UI & Conversion Scoring. Score product pages, category pages, search, navigation, cart, checkout where accessible, mobile usability, performance, content and technical quality.

03 — Executive Audit Report. Reproduce the supplied report's overall score, score-by-area bars, KPI cards, essential fixes, recommended improvements, content updates, strengths and opportunities.

04 — Commercial Opportunity Engine. Connect each verified problem to a relevant Smollan Digital Commerce service, produce a lead qualification summary, and draft a personalised business-development approach.

The commercial logic is particularly important. eComplete Commerce's published capabilities include ecommerce development, UX and design, performance optimisation, data and product management, marketing, CRM, customer service, and fulfilment. These provide a credible starting point for matching audit findings to potential services.

The application should use the current Smollan Digital Commerce identity in its report and outreach, while allowing the ecompletecommerce.co.za website to inform the service catalogue during the transition.

2. How the report should replicate your example

The attached report should become the application's primary report specification, rather than merely a visual reference.

Report overview

Brand header, audit period, website summary and executive verdict.

OVERALL SCORE: 66/100 — Needs improvement

AUDIT FINDINGS: 34 (illustrative reference figure)

These values illustrate the layout in your reference; a new audit must calculate its own results.

Score by area (illustrative values from the design concept, not results from a live website)

- Product pages: 50%
- Header and footer: 58%
- Cart: 62%

- Mobile usability: 67%
- Listings and search: 79%
- Checkout: 80%
- Delivery and returns: 80%
- Error pages: 83%

Key metrics — current audit vs previous audit

- Sessions: Analytics
- Page speed: Measured
- Engagement: Analytics
- Scroll depth: Analytics
- High intent: Defined
- Dead clicks: Observed
- Performance score: Measured
- Accessibility: Tested
- Conversion: Analytics

What needs to happen

- **ESSENTIAL** — Fixes required before a target date. Broken purchase journeys, unusable controls, serious mobile issues and other high-impact barriers.
- **RECOMMENDED** — Conversion and usability improvements. Product reviews, filtering, product-card improvements, navigation and layout refinements.
- **CONTENT & SETTINGS** — Merchandising and information gaps. Product descriptions, size guides, delivery information, pricing clarity and promotional presentation.

What is working / Opportunities to improve

Two evidence-based summaries, followed by the three to five highest-priority actions and a recommended next step.

The final report should preserve the reference's compact, executive-friendly layout, navy header, bright cyan accents, colour-coded score bars, metric tiles and action cards. It should also provide a drill-down report showing the evidence behind each finding.

3. The master prompt for Google AI Studio

Open Google AI Studio at aistudio.google.com and select Build to create a web application. Build mode can generate the initial application from a natural-language specification and show a live preview.

Paste the following as your primary build prompt. It is deliberately detailed so the initial application has a clear scope, scoring model and report structure.

Master build prompt: Smollan Digital Commerce · Website Intelligence & Opportunity Audit

The following is the full specification to paste into Build mode. If the builder struggles with its length, use the staged implementation prompts in section 7.

PROJECT: SMOLLAN DIGITAL COMMERCE — WEBSITE INTELLIGENCE & OPPORTUNITY AUDIT

1. YOUR ROLE

Act as a senior full-stack engineer, ecommerce conversion-rate optimisation specialist, UX/UI auditor, technical SEO analyst, web performance engineer, accessibility evaluator and B2B business-development strategist.

Build a functional, production-minded web application for Smollan Digital Commerce.

The application must accept a publicly accessible ecommerce or business website URL, inspect the website and its accessible internal pages, evaluate its customer experience, calculate a transparent score by area, identify evidence-backed opportunities for improvement, and generate a polished report that can be used as a credible sales-enablement asset.

This is not merely a chatbot, static dashboard, website summariser or mockup. Build the application and its actual audit workflow.

2. BUSINESS OBJECTIVE

The application has two purposes:

1. Provide a useful, credible and actionable website audit to a prospective client.

2. Help Smollan Digital Commerce identify and qualify potential commercial opportunities based on verified website findings.

Use https://ecompletecommerce.co.za/ as an initial reference for service discovery. Review its public service pages and maintain an editable service catalogue. Where the business website redirects or its branding changes, retain configurable company identity, website URL, logo, service descriptions and contact details.

Position the application as a Smollan Digital Commerce website assessment. Do not imply that the assessed company is already a customer, that Smollan has a relationship with it, or that Smollan has conducted a full professional engagement.

3. APPLICATION STACK

Build a responsive full-stack web application using:

- React and TypeScript for the frontend.
- Node.js for server-side crawling, processing and API routes.
- Google Gemini through the supported server-side SDK.
- Playwright or an appropriate headless-browser solution for rendered page inspection, subject to runtime compatibility.
- Cheerio or equivalent HTML parsing for efficient page extraction.
- Lighthouse/PageSpeed Insights or equivalent measurement tools where available and practical.
- axe-core or equivalent accessibility checks where technically feasible.
- A charting library for score visualisations.
- A reliable PDF generation approach and a print-ready HTML report.
- A database abstraction for audit history, saved leads and report metadata.

Use current, supported package versions. Verify compatibility before installing packages.

Keep API keys and secrets server-side. Never expose Gemini credentials, private tokens or third-party API keys in browser code.

If a browser automation dependency cannot run in the deployment environment, implement a clearly identified alternative using server-side HTML extraction and supported external measurement APIs. Do not simulate a browser audit or represent a static HTML analysis as a fully rendered inspection.

4. APPLICATION NAVIGATION

Create these sections:

A. Overview dashboard

B. New website audit

C. Audit progress

D. Audit report

E. Findings explorer

F. Lead qualification and opportunity mapping

G. Saved audits and leads

H. Settings and service catalogue

The primary call to action must be "Start a website audit".

The new audit form should request:

- Website URL.
- Business or brand name, optional.
- Business category, optional.
- Target country or market, optional.
- Primary objective: sales, lead generation, bookings, subscriptions or general experience.
- Audit depth: quick scan, standard audit or deep audit.
- Device focus: desktop, mobile or both.
- Optional comparison website.
- Optional client-provided analytics or performance data.

Do not require the user to know technical details before starting an audit.

5. WEBSITE CRAWLER

Implement a real, controlled website crawler.

The crawler must:

1. Normalise and validate the submitted URL.

2. Confirm that the initial host is publicly reachable.

3. Read robots.txt and sitemap.xml where available.

4. Discover internal links from sitemaps, navigation, page content and relevant structured data.

5. Stay within the approved domain and permitted subdomains.

6. Deduplicate URLs by canonical URL, normalised path and appropriate query-parameter rules.

7. Identify page types such as homepage, category, product detail, search results, cart, checkout, campaign, contact, help, delivery, returns and policy pages.

8. Record HTTP status codes, redirects, canonical tags, title tags, descriptions, headings, internal links, image attributes, structured data, form controls and important page elements.

9. Inspect responsive layouts at appropriate desktop and mobile viewport sizes.

10. Record failed requests, blocked pages, timeouts, inaccessible pages and crawl limits.

11. Show the pages discovered, pages successfully inspected and pages skipped.

12. Allow the operator to inspect the discovered page list and exclude pages before or during the audit where feasible.

Provide configurable limits for page count, crawl depth, timeout, concurrency and total audit duration.

Suggested defaults:

- Quick scan: up to 5 pages.
- Standard audit: up to 25 pages.
- Deep audit: up to 100 pages.

These are initial product limits, not guarantees. Apply sensible lower limits when required by runtime, website restrictions or available measurement capacity.

Use rate limiting, conservative concurrency, caching and per-host request delays.

Do not bypass authentication, CAPTCHAs, paywalls, bot protection or access controls. Do not attempt purchases, submit real customer data, place orders or alter production websites.

Checkout pages must be inspected only when legitimately accessible without completing a transaction. Clearly disclose checkout coverage limitations.

6. CRAWLER SECURITY

Treat the crawler as an internet-facing service that may be given hostile URLs.

Implement server-side protections against SSRF, DNS rebinding, open redirects and access to internal infrastructure.

- Allow only HTTP and HTTPS.
- Reject localhost, private, loopback, link-local, reserved and cloud metadata addresses.
- Resolve and validate DNS results before connecting.
- Revalidate every redirect destination.
- Reject redirects to disallowed hosts or address ranges.
- Prevent access to internal services and non-public IP ranges.
- Enforce response-size, timeout and decompression limits.
- Limit concurrent jobs and requests per host.
- Do not execute untrusted downloaded code.
- Treat page content as untrusted data, not as instructions for the AI model.
- Do not allow website content to override the system prompt or trigger tools.
- Never send credentials, private application data or API keys to the website being audited.

Keep crawl logs sufficient for troubleshooting without unnecessarily storing sensitive data.

7. EVIDENCE COLLECTION

For every inspected page, collect the evidence necessary to support the assessment.

Examples include:

- URL and page classification.
- Page title, meta description and heading hierarchy.
- Navigation structure and breadcrumbs.

- Visible buttons, links, forms and calls to action.
- Product name, price, availability indicators, image count and variant selectors.
- Product descriptions and supporting product information.
- Search controls, category filters, sort controls and pagination.
- Cart access and visible delivery, returns and payment information.
- Image dimensions, missing alt attributes and oversized image indicators where measurable.
- Broken internal links and HTTP errors.
- Responsive layout issues and horizontal overflow where detectable.
- Form labels, accessible names, contrast and keyboard navigation where tested.
- Core Web Vitals and Lighthouse results only when actually measured.
- Page screenshots when supported.
- Timestamp and method of each measurement.

Each finding must identify the affected URL, observed element or condition, evidence, severity, confidence, business implication and proposed remedy.

Store the distinction between:

- Observed and directly measured facts.
- Automated rule-based findings.
- AI-generated interpretations.
- Hypotheses requiring human validation.
- Metrics that are unavailable.

Never invent evidence or fabricate screenshots.

8. SCORING FRAMEWORK

Create a transparent scoring model using a 0–100 scale.

Evaluate these categories:

1. Product detail pages.
2. Header, navigation and footer.
3. Cart and mini-cart.
4. Mobile usability and responsive behaviour.
5. Category listings, filtering and search.
6. Checkout and purchase journey.
7. Delivery, returns, payment and commercial policies.
8. Error handling and recovery.
9. Content quality and merchandising.
10. Technical performance and Core Web Vitals.
11. Accessibility and inclusive interaction.
12. Technical SEO and discoverability.

13. Trust signals, customer support and reassurance.

Use configurable category weights. Start with these default weights:

- Product detail pages: 15%
- Header, navigation and footer: 8%
- Cart: 10%
- Mobile usability: 10%
- Listings and search: 10%
- Checkout: 12%
- Delivery and returns: 6%
- Error handling: 4%
- Content and merchandising: 7%
- Technical performance: 7%
- Accessibility: 4%
- Technical SEO: 4%
- Trust and support: 3%

These weights total 100%. Allow administrators to adjust them and retain a versioned record of the weighting model used for each audit.

Calculate each category score from explicit checks, with each check assigned:

- A weight.
- A pass, partial pass, fail, not applicable or not assessed status.
- Evidence.
- A severity and confidence rating.

Convert weighted check results into a category score. Calculate the overall score from the configured category weights and valid category scores.

Do not treat an inaccessible page or unmeasured metric as a successful result.

Report category coverage separately from score. When a critical category is unavailable, display a provisional overall score or a clearly labelled limited-coverage assessment.

The report must explain how the score was calculated and what the score does and does not establish.

9. PRIORITY AND REMEDIATION

Classify findings into three action groups:

A. ESSENTIAL — High-impact barriers, broken purchase journeys, serious usability failures, critical technical errors or urgent accessibility issues. Use a deadline only when configured by the operator.

B. RECOMMENDED — Material conversion, navigation, search, mobile, performance or usability improvements that merit prioritisation.

C. CONTENT AND SETTINGS — Product descriptions, imagery, merchandising, policies, delivery information, metadata, promotional presentation and configuration improvements.

For each finding, show:

- Finding ID.

- Title.
- Category.
- Affected URL.
- Observed evidence.
- Expected user impact.
- Commercial rationale.
- Severity.
- Confidence.
- Estimated implementation effort: low, medium or high.
- Priority score.
- Proposed resolution.
- Relevant Smollan Digital Commerce service.
- Whether human verification is required.

Prioritise findings using a transparent formula based on impact, severity, confidence and effort. Display the underlying factors rather than presenting the ranking as an unexplained AI opinion.

Do not assign guaranteed revenue values or estimated conversion uplifts without a documented calculation and adequate evidence.

10. REPORT DESIGN — MATCH THE SUPPLIED REFERENCE

Use the attached Reebok UX/UI report as the primary visual and information-architecture reference.

Reproduce the following report sections:

1. Branded header with logo, audit label, reporting period and a short executive introduction.

2. Overall score panel showing score out of 100 and a plain-language interpretation.

3. Summary tiles for total findings, essential fixes, recommended improvements and content updates.

4. Executive verdict describing the strongest area and the weakest area.

5. Score-by-area horizontal bars with colour-coded performance ranges.

6. Key metrics section showing available measurements, values and comparisons with a previous audit when available.

7. Essential fixes card.

8. Recommended improvements card.

9. Content and settings updates card.

10. What's working summary.

11. Opportunities to improve summary.

12. A final next-step recommendation.

13. Detailed findings appendix with evidence and affected URLs.

14. Methodology, limitations, coverage and audit timestamp.

Use a professional Smollan Digital Commerce visual identity:

- Deep navy blue.

- Bright cyan accents.
- Restrained green and amber accents.
- Red or coral for low-scoring areas.
- Light grey-blue cards.
- Clean typography, generous spacing and compact executive-friendly layouts.

Use a responsive, print-ready layout. The report must remain legible on desktop, mobile and PDF.

Provide:

- In-app report.
- Print-ready HTML.
- PDF export.
- JSON export of the structured audit results.
- Shareable report link only where access controls are implemented.

Do not hardcode the sample values from the reference. Calculate every score, count and measurement from the current audit data.

11. KEY METRICS

Reproduce the reference's KPI strip while supporting additional meaningful metrics.

Possible metrics include:

- Sessions.
- Unique users.
- Pages per session.
- Scroll depth.
- Active time.
- High-intent interactions.
- Quick backs.
- Dead clicks.
- Performance score.
- Largest Contentful Paint (LCP).
- Interaction to Next Paint (INP).
- Cumulative Layout Shift (CLS).
- First Contentful Paint (FCP).
- Accessibility findings.
- Broken links.
- Product-page coverage.
- Crawl coverage.

Every metric must include a source and availability status.

Separate the following data classes:

A. Directly measured during the audit.

B. Provided by the customer.

C. Imported from an authorised analytics integration.

D. Not available.

Do not estimate sessions, unique users, conversion rate, engagement, scroll depth, dead clicks or historical changes from public HTML.

Dead clicks and quick backs generally require browser interaction telemetry or analytics instrumentation. Display these as unavailable unless an appropriate data source provides them.

Performance scores must be linked to the actual tool, measurement date, device profile and tested URL.

Comparisons between audit periods are allowed only where comparable prior measurements exist.

12. AI ANALYSIS

Use Gemini to interpret the collected evidence and write concise, professional findings.

The model must:

- Receive structured evidence rather than relying solely on a URL.
- Explain why each finding matters.
- Suggest practical remedies.
- Identify which findings could affect conversion or customer confidence.
- Match problems to relevant services.
- Produce an executive summary.
- Identify the strongest and weakest areas.
- Distinguish facts from hypotheses.
- Return structured JSON matching a defined schema.
- Avoid duplicating findings across pages.
- Cite the exact audited URL for each claim.
- State when the evidence is insufficient.

The deterministic scoring engine, not free-form model judgement, must calculate the final score.

Validate model outputs against the schema and reject unsupported claims.

13. SMOLLAN DIGITAL COMMERCE SERVICE MAPPING

Build an editable service catalogue based on publicly documented services, initially informed by https://ecompletecommerce.co.za/.

Consider service categories including:

- Ecommerce strategy and consulting.
- Ecommerce website development and migration.
- UX/UI and conversion-rate optimisation.
- Website performance and technical optimisation.
- SEO and digital marketing.
- Product catalogue and merchandising management.

- Analytics and business intelligence.
- Customer relationship management and customer service.
- Email and WhatsApp marketing.
- Hosting and security.
- Fulfilment and operational integration.
- Marketplace and multichannel commerce.
- B2B commerce.
- International expansion and localisation.

Verify the current public service descriptions before using them in reports. Make service descriptions editable by authorised administrators.

For every major finding, identify:

1. The observed problem.

2. The service that could address it.

3. The likely scope of work.

4. Why a conversation with Smollan may be worthwhile.

5. Any uncertainty that requires discovery before a proposal can be made.

Do not imply that a specific service is available under a particular contract unless verified.

14. LEAD QUALIFICATION

Generate a structured opportunity profile for the audited business.

Include:

- Business and domain.
- Business category where known.
- Ecommerce platform where reliably detected.
- Geographic market where supplied or supported by evidence.
- Overall audit score.
- Audit coverage and confidence.
- Top five verified findings.
- Main potential service opportunities.
- Suggested discovery questions.
- Recommended first conversation topic.
- Lead priority: high, medium or low.
- Reason for the priority.
- Human review status.

Lead priority must be based on documented signals, not invented company size, revenue, traffic, technology spend or purchasing intent.

A low score alone must not automatically qualify a lead as high priority.

Generate a concise, professional, personalised outreach draft using the strongest verified findings. Make it editable before use.

Do not send emails, submit forms, contact the business, or initiate outreach automatically. Require explicit human approval for all external communications.

15. AUDIT HISTORY AND ADMINISTRATION

Implement an initial persistence layer for:

- Audit jobs.
- Page inventory.
- Structured findings.
- Scores and score-model versions.
- Reports.
- Leads.
- Service mappings.
- Audit timestamps.
- Errors and coverage limitations.

Allow users to reopen past audits and compare reports.

Distinguish a new audit from a historical audit. Do not claim improvement or deterioration unless measurements are comparable.

Provide configurable retention and deletion controls. Require authentication before exposing private reports or saved prospect records.

Do not store unnecessary personal data.

16. USER EXPERIENCE

Create a polished dashboard with:

- Website URL input.
- Start audit button.
- Audit depth selector.
- Crawl progress.
- Pages discovered and inspected.
- Category scores.
- Findings by priority.
- Executive report preview.
- Lead opportunity summary.

Show useful progress states, including:

- Validating URL.
- Discovering pages.
- Inspecting content.
- Measuring performance.

- Evaluating UX and accessibility.
- Generating findings.
- Calculating scores.
- Preparing report.

Support retries and partial results if some pages fail.

Clearly communicate when an audit is incomplete.

17. ACCEPTANCE TESTS

The application is not complete until:

1. A user can submit a valid public URL and start an audit.

2. The server discovers and inspects real accessible pages.

3. The application records actual page-level evidence.

4. Scoring is calculated from explicit rules and configured weights.

5. Missing metrics are labelled unavailable.

6. Findings link to the affected URLs.

7. Findings can be prioritised and mapped to services.

8. The executive report follows the supplied reference layout.

9. The report can be printed and exported.

10. The crawler rejects private network targets and unsafe redirects.

11. Gemini API credentials remain server-side.

12. The application handles crawl failures without fabricating results.

13. A user can inspect why a category received its score.

14. A user can review a lead profile and edit an outreach draft.

15. No external email or website modification occurs without explicit approval.

18. IMPLEMENTATION INSTRUCTIONS

Build in phases, but deliver a working application at each stage.

Phase 1: Create the responsive dashboard, URL form, server-side audit endpoint, real limited-depth crawler, page inventory and report shell.

Phase 2: Add category scoring, structured evidence extraction, Gemini findings, priority classification and service mapping.

Phase 3: Add browser-based responsive inspection, performance testing, accessibility checks and screenshot capture where supported.

Phase 4: Add PDF export, saved audits, lead qualification, comparison reports and outreach drafting.

Phase 5: Add authentication, persistent storage, operational controls, automated tests and deployment hardening.

Start with Phase 1. Do not stop at a static visual prototype. Build the actual workflow, run it against a public test website, inspect the generated results, correct errors and then extend the implementation.

Before declaring completion, report which features work, which remain limited, which dependencies require configuration and which acceptance tests have passed.

4. Scoring model: how to make the audit credible

I recommend a distinction between the website experience score and the commercial opportunity score. They answer different questions.

- Website experience score: How well does the website perform against defined usability, content, technical and conversion criteria?
- Commercial opportunity score: How strong is the evidence that the business could benefit from one or more Smollan services?

A website can score poorly but still be a weak prospect for commercial reasons. Equally, a technically strong website may have a meaningful opportunity in analytics, fulfilment, CRM or multichannel operations.

Proposed category weighting

Audit area	Weight
Product detail pages	15%
Header, navigation and footer	8%
Cart and mini-cart	10%
Mobile usability	10%
Category listings and search	10%
Checkout and purchase journey	12%
Delivery and returns	6%
Error handling	4%
Content and merchandising	7%
Technical performance	7%
Accessibility	4%
Technical SEO	4%
Trust and customer support	3%
Total	100%

These weights are a proposed starting point, not an industry benchmark. Administrators should be able to change them and version the scoring model.

Example of a finding and its score impact

Example finding: Product descriptions are missing. Priority: High. (Hypothetical result — not a finding from a live audit.)

Evidence: Three of eight inspected product pages contain no meaningful descriptive copy beyond the product title.

Potential impact: Customers may lack information needed to assess product suitability, compare products and make purchasing decisions.

Potential service fit: Product catalogue optimisation, merchandising and UX/conversion optimisation.

Verification: Link each affected product page and retain the inspected text or screenshot. Do not extrapolate the finding to the entire catalogue without sufficient coverage.

How the scoring engine should work

For each audit area:

1. Run specific checks against the collected evidence.
2. Assign each check a configured weight.
3. Record pass, partial pass, fail, not applicable or not assessed.
4. Calculate the category score from assessed, applicable checks.
5. Calculate the overall weighted score from eligible category scores.
6. Display the percentage of the audit that was successfully assessed.

A category with no usable evidence must be marked Not assessed, rather than given a score of zero or 100. The report should explain any resulting limitations.

5. Reproduce the metrics without inventing data

This is one of the most important requirements because the reference report combines website observations with behavioural analytics.

Metric from the reference	Can a public website audit provide it?	Required treatment
Overall performance score	Yes, if calculated from defined checks	Calculate from the scoring engine
Number of findings	Yes	Count distinct, validated findings
Essential fixes	Yes	Count findings classified as essential
Content updates	Yes	Count findings classified as content-related
Sessions and unique users	No, not from public HTML alone	Require authorised analytics data
Pages per session	No, not from public HTML alone	Require analytics data
Scroll depth and active time	Not reliably from a crawler alone	Require behavioural analytics or instrumentation
High-intent interactions	Only with suitable event data or a defined proxy	Label the source and method
Quick backs and dead clicks	Generally require behavioural instrumentation	Show as unavailable unless measured
LCP, INP and CLS	Potentially, with an appropriate performance test	Record actual measurements and test conditions
Previous-period changes	Only with comparable historical data	Compare stored, comparable audits or analytics

The system should support three states for each metric: Measured, Customer data required, and Unavailable.

It should never fill an empty KPI tile with a guessed number just to reproduce the reference design. If no previous audit exists, show a current value and omit the change indicator or label it as a baseline.

6. Make the report generate business opportunities

The report should do more than tell a prospect that their website has problems. Each significant finding should create a structured bridge between the problem and a relevant service.

The existing eComplete Commerce site describes services including website development, UX/design, performance optimisation, product management, business intelligence, customer service and fulfilment. These are sensible starting mappings, subject to verifying the current service offering.

Example opportunity mapping

- Weak mobile product experience — UX/UI and conversion optimisation. Improve usability of product selection and purchase actions on mobile devices.
- Poor catalogue content — Data and product management. Improve product descriptions, attributes, images and merchandising consistency.
- Slow page rendering — Performance optimisation and technical services. Investigate measured bottlenecks and prioritise technical remediation.
- Limited visibility into customer behaviour — Business intelligence and growth consulting. Establish an evidence-based measurement framework if analytics coverage is inadequate.
- Disconnected post-purchase experience — CRM, customer service and fulfilment. Explore operational integration, communication and customer journey improvements where evidence supports the need.

For each prospect, generate a concise internal opportunity brief with:

- Website and business name.
- Overall audit score and coverage.
- Three to five strongest findings.
- Recommended service lines.
- Why each service is relevant.
- Discovery questions to qualify the opportunity.
- Lead priority with an explanation.
- Suggested opening topic for a business-development conversation.
- Draft outreach for human review.

The application should not send the outreach automatically. Its job is to make prospecting more informed and efficient, not to automate unsolicited communications without review.

7. The best approach to begin building it

I would not ask Google AI Studio to implement every feature in one attempt and assume the result works. The full specification defines the destination, but staged implementation is more likely to produce a functioning crawler, accurate scoring and a report you can trust.

Use these prompts in sequence in the same project.

Stage 1 — Build the working foundation

Start here. Create the application, not just the mockup.

Build Phase 1 of the Smollan Digital Commerce Website Intelligence & Opportunity Audit application.

Create a polished, responsive React and TypeScript web application with a Node.js backend.

The first screen must contain:

- Smollan Digital Commerce branding.
- A website URL input.
- Optional business name and industry.
- An audit depth selector: Quick Scan, Standard Audit and Deep Audit.
- A Start Audit button.
- A recent audits section.

- A professional executive dashboard with category score bars, finding counts and priority summaries.

Implement a working server-side website crawler. Validate the submitted URL, reject private or internal network destinations, inspect robots.txt and sitemaps where available, discover internal links and extract real page content and HTML metadata.

For the initial version, inspect up to five accessible pages. Record each URL, HTTP status, page title, description, headings, links, page type, visible calls to action and available product information.

Display actual crawl progress and a page inventory showing inspected, skipped and failed pages.

Build a basic rule-based scoring engine for product pages, navigation, listings and search, cart, mobile usability, content, delivery information, technical SEO and performance where measurable.

Create an executive report that follows the supplied Reebok UX/UI report's layout. Use deep navy, cyan accents, light grey-blue cards and colour-coded score bars.

Every result must come from actual inspection or be clearly labelled as unavailable. Do not populate the report with fabricated audit data.

Use Gemini only through the server-side runtime. Keep secrets out of client-side code.

Implement error handling, safe crawl limits and a visible coverage indicator.

Before finishing, run the application, test it against a publicly accessible website, inspect the actual results and fix any build or runtime errors. Report any functionality that remains incomplete.

Prioritise a working audit pipeline over decorative features.

Stage 2 — Add evidence-backed AI analysis

After the initial crawl works.

Extend the existing application without replacing working functionality.

Implement the full configurable scoring model specified in the project requirements. Create explicit, weighted checks for every audit category and calculate category and overall scores deterministically.

Add Gemini-powered analysis using structured evidence extracted by the crawler. Return validated structured findings with the affected URL, observed evidence, business impact, severity, confidence, implementation effort, proposed remedy and verification status.

Create Essential, Recommended, and Content & Settings action groups. Add category coverage and clearly distinguish measured facts, rule-based findings, AI interpretations and hypotheses.

Implement the complete score-by-area report, findings appendix, strengths, opportunities and executive summary.

Never infer missing analytics metrics, invent evidence or let Gemini choose the numerical score without applying the scoring rules. Include a methodology section explaining weights, coverage and limitations.

Test the calculation logic with known inputs, including inaccessible pages, not-applicable checks, missing evidence and partial coverage.

Stage 3 — Add the sales opportunity engine

Turn audit findings into qualified leads.

Extend the existing audit application into a Smollan Digital Commerce lead-generation platform.

Create an editable service catalogue informed by the publicly documented services at https://ecompletecommerce.co.za/. Verify current service descriptions and keep all service mappings configurable.

Map verified audit findings to relevant services, explaining the relationship between the observed problem, the proposed service and the discovery questions needed to qualify the opportunity.

Create a prospect profile containing business name, domain, audit score, coverage, verified findings, relevant service lines, qualification rationale, lead priority and recommended next step.

Do not invent revenue, traffic, company size, budget, buying intent or decision-maker details.

Generate an editable, personalised outreach draft using only verified findings. Do not send messages or contact businesses automatically.

Add saved leads, saved audits, historical comparisons where comparable data exists, filters, report export and an executive opportunity dashboard.

Include human review and approval controls for all external communications. Ensure private reports and prospect records are protected by appropriate authentication and access controls.

Test the entire workflow from website submission through audit, report, lead qualification and outreach drafting.

Stage 4 — Production readiness

Harden the application before sharing it externally.

Review the entire existing application for production readiness.

Test URL validation, SSRF protection, DNS resolution, redirects, robots.txt handling, crawl limits, concurrency, timeouts, response-size limits, failed pages, malicious page content and prompt injection.

Review server-side secrets, authentication, access controls, persistent storage, error logging, rate limits, data retention and deletion.

Verify that scores are reproducible, report values match the stored audit results, unavailable metrics are never fabricated, and exported reports accurately represent the inspected pages.

Test the PDF and print layouts against the supplied report reference on desktop and mobile.

Run available unit, integration and end-to-end tests. Fix defects rather than merely describing them. Do not mark a test as passed unless it was actually executed.

Provide a final checklist distinguishing implemented, tested, partially implemented and unimplemented features. Identify any required third-party credentials, billing, browser infrastructure or deployment configuration.

Do not publish the application or make external changes without explicit approval.

8. Important implementation decisions

These are the areas I would insist on getting right before treating this as a sales tool.

1. **Protect the crawler.** An application that accepts arbitrary URLs must be protected against server-side request forgery (SSRF), unsafe redirects and access to internal network resources. This is a server-side security requirement, not something Gemini can handle reliably through prompting alone.

2. **Separate measurements from AI opinions.** Browser inspection and rule-based checks should establish what was observed. Gemini should interpret the evidence and explain why it matters. The numerical scoring engine should remain deterministic and testable.

3. **Treat analytics as a separate integration.** Public website crawling cannot reveal private Shopify sales, conversion rates or behavioural analytics. Add authorised analytics integrations later, with appropriate consent and permissions. Do not let the absence of these metrics prevent a useful UX audit.

4. **Make every score explainable.** A prospect or Smollan consultant should be able to click a 50% product-page score and see which checks failed, which pages were inspected, what evidence was captured and how the score was calculated.

5. **Keep sales qualification evidence-based.** Do not treat the worst-scoring websites as automatically the best leads. Combine verified website problems, service fit, business context and any legitimate qualification information supplied by the user.

Google AI Studio supports server-side secrets for Gemini integrations, but deployment and production requirements still need to be verified. A deployed application may incur API or hosting costs depending on the account, configuration and usage.

9. How I would launch the first version

MVP launch checklist

- Build the initial dashboard and URL input — Create the application shell and audit submission.
- Crawl a real public website — Verify page discovery, HTML extraction and crawl safety.
- Generate the first evidence-backed score — Validate checks and category weighting.
- Render the Reebok-style report — Confirm report sections, visual hierarchy and print layout.
- Map findings to Smollan services — Verify the service catalogue and opportunity rationale.
- Test lead output and export — Review the saved audit, PDF and editable outreach draft.

My recommendation is to start with the five-page crawl, transparent scoring, report generation and service mapping. That is enough to demonstrate the concept to internal stakeholders and test whether the output would genuinely help the business-development team.

Once the results are reliable, extend the crawler, add browser-based performance and accessibility testing, introduce persistent lead management, and integrate authorised analytics where customers can provide access.

The end product should feel like a professional Smollan Digital Commerce assessment — not a generic AI-generated website review — and should make it easy to move from verified website issue to relevant service to qualified sales conversation.
